MAXIMA OF MOVING SUMS IN A POISSON RANDOM FIELD

HOCK PENG CHAN,* National University of Singapore

Abstract

We examine here the extremal tail probabilities of moving sums in a marked Poisson random field. These sums are computed by adding up the weighted occurrences of events lying within a scanning set of fixed shape and size. We also provide an alternative representation of the constants of the asymptotic formulae in terms of the occupation measure of the conditional local random field at zero and extend these representations to the constants of asymptotic tail probabilities of Gaussian random fields.

Keywords: Change of measure; Gaussian process; large deviations; marked Poisson process; moving sums; random field; scan statistics.

Secondary 60G10; 60G55

1. Introduction

The maxima of moving averages in Gaussian random fields in dimension $d > 1$ was studied in [19], [21], with applications in imaging and signal detection. Two key techniques used are (i) the Karhunen-Loève expansion with the volume of tube formula

*Postal address: Department of Statistics and Applied Probability, Faculty of Science, National University of Singapore, Science Drive 1, Singapore 119260
Email: stachp@nus.edu.sg
and (ii) the Euler characteristic; see [1] for an overview and [24], [25] for more recent developments.

The maxima of moving sums in Poisson random fields, more commonly known as scan statistics in the statistical literature, is also used widely in molecular biology, epidemiology, geostatistics and image analysis, cf. [4], [8], [9], [11], but the tail probability approximations are in comparison not as well developed for $d > 1$. While the tail probabilities of these sums have been studied in [3], [14], [15], restrictions to rectangular scanning sets have been imposed for analytical convenience.

We set out here to study the tail probabilities of the maxima of moving sums for a wider choice of scanning sets. A theory parallel to the study of tail probabilities in Gaussian or Gaussian-like random fields in the classical framework of Pickands [16] and Qualls and Watanabe [18] (see also [7], [17]) is first developed. Motivated by recent developments in molecular biology, see for example [8], we consider a more general marked Poisson random field. This generalization entails careful consideration of overshoots in special cases of scanning sets that is not required in Poisson random fields. Albin [2] and Berman [5] studied tail probabilities of stationary processes but their limiting results are of a different type and do not apply here. Kabluchko and Spodarev [13] considered scan statistics of Lévy noises and marked empirical processes, with the scan over all cubic subsets of $[0,1]^d$.

The main results of this paper are Theorems 2.1 and 2.2. We illustrate their applications with examples in Section 3. Theorem 2.1 provides an expression of the asymptotic tail probability and the statement of the result requires a description of an induced local random field around the boundary of the scanning set. The proof of Theorem 2.1 is given in Section 4. Lemma 4.1 is the basic building block of Theorem
2.1, providing the extremal tail probability over a local domain by using a change of
measure approach. We then show how these building blocks can be combined together
to provide the tail probability of the maxima of the sums over the whole domain,
via an adaption of the Pickands-Qualls-Watanabe technique. Theorem 2.2 provides
an alternative representation of the asymptotic constants in terms of the occupation
measure of the local random field at zero. The proof is given in Section 5. We extend
the representation to Gaussian random fields in Section 6. These representations
provide simple upper and lower bounds of the asymptotic constants, see the examples
in Sections 3 and 6. We consolidate the technical details in the appendices.

2. Main results

For vectors $t = (t_1, \ldots, t_d)$, $u = (u_1, \ldots, u_d)$ and real number $b$, we shall let $t \geq u$
denote $t_j \geq u_j$ for all $j$ and $t \geq b$ to denote $t_j \geq b$ for all $j$. Let $\sigma_k(\cdot)$, $k = d$ or $k = d - 1$,
denote the Lebesgue or Hausdorff measure of a $k$-dimensional manifold in $\mathbb{R}^d$. For any
$A \subset \mathbb{R}^d$, real number $b$ and $t \in \mathbb{R}^d$, let $\#A$ denote the number of elements in $A$ and
t + bA = \{t + ba : a \in A\}. Also let $\|t\| = \sqrt{t_1^2 + \cdots + t_d^2}$ and $\|t\|_\infty = \max_{1 \leq j \leq d}|t_j|$.

Let $B$ be a bounded subset of $\mathbb{R}^d$ with boundary $\partial B$ that can be expressed as a finite
union of smooth $(d-1)$-dimensional submanifolds possibly with boundary (see p. 113 of
[22] for the definition), satisfying $\sigma_{d-1}(\partial B) < \infty$. For example if $B = \{t : \|t\|_\infty \leq 1\}$,
a cube of length 2 centered at 0, then $\partial B$ is a union of $2d$ faces, each a smooth $(d-1)$-
dimensional submanifold with boundary.

Let $\{t_i : i \geq 1\}$ be a homogeneous Poisson point process on $\mathbb{R}^d$ with intensity $\lambda > 0$
and let $X_1, X_2, \ldots$ be independent and identically distributed (i.i.d.) random variables
having distribution $F$ and independent of the Poisson point process. Let $\mathcal{X} = \{(t_i, X_i) : i \geq 1\}$ denote the marked point process. Let $\mu = E(X_1)$ and $M(\theta) = E(e^{\theta X_1})$. Assume that $\Theta = \{\theta : M(\theta) < \infty\}$ is an open neighborhood of 0. For any $A \subset \mathbb{R}^d$, define the sum $S(A) = \sum_{t_i \in A} X_i$. Let $D$ be a Jordan measurable (bounded) subset of $\mathbb{R}^d$ and let $c > \mu \sigma_d(B)$. We analyze here the tail probability

$$p_\lambda = P_\lambda \left( \sup_{v \in D} S(v + B) \geq \lambda c \right) \quad \text{as } \lambda \to \infty. \quad (2.1)$$

Through an appropriate transformation, we can also look at the limiting probability of $p_\lambda$ as one involving fixed Poisson rate $\lambda_0 > 0$ and increasingly large scanning sets. Let $g_\lambda = (\lambda/\lambda_0)^{1/d}$ be the scaling constants. Then $p_\lambda = P_{\lambda_0} \{ \sup_{v \in g_\lambda D} S(v + g_\lambda B) \geq \lambda c \}$.

For notational simplicity, the analysis here looks at $p_\lambda$ in terms of (2.1) but in terms of practical use, the asymptotics in terms of increasing scanning sets is sometimes more appropriate.

We will now proceed with the description of a limiting local random field $Y$ that is derived from both the distribution $F$ and the geometry of the boundary $\partial B$. Let $\theta_c > 0$ and distribution $F_c$ satisfy

$$M'(\theta_c) = c/\sigma_d(B)\quad \text{and} \quad F_c(dx) = e^{\theta_c x} F(dx)/M(\theta_c), \quad (2.2)$$

where $'$ here denotes first derivative. By (2.2), a random variable having distribution $F_c$ has mean $M'(\theta_c)/M(\theta_c) = c/\sigma_d(B)M(\theta_c)$ and hence a marked Poisson process with intensity $\lambda M(\theta_c)$ and mark distribution $F_c$ inside $B$ will satisfy $E_*[S(B)] = \lambda c$.

Consider the product space $\partial B \times \mathbb{R}$ with measure induced from the $(d-1)$-dimensional Hausdorff measure on $\partial B$ and Lebesgue measure on $\mathbb{R}$. Let $\{v_i : i \geq 1\}$ be a nonhomogeneous Poisson point process on $\partial B \times \mathbb{R}$ with intensity 1 on $\partial B \times [0, \infty)$ and intensity $M(\theta_c)$ on $\partial B \times (-\infty, 0)$. Let $Z_1, Z_2, \ldots$ be independent random variables
(marks) conditioned on this nonhomogeneous point process, with \( Z_i \sim F \) if \( v_i \in \partial B \times [0, \infty) \) and \( Z_i \sim F_c \) if \( v_i \in \partial B \times (-\infty, 0) \). Let \( Q_\lambda \) be a probability measure under which \( X = \{(t_i, X_i) : i \geq 1\} \) is a nonhomogenous marked point process with intensity \( \lambda M(\theta_c) \), mark distribution \( F_c \) inside \( B \) and intensity \( \lambda \), mark distribution \( F \) outside \( B \). The measure \( Q_\lambda \) describes the local behavior of \( X \) near \( \partial B \) under the original probability measure \( P_\lambda \) in which \( X \) is homogeneous, when conditioned on \( \{S(B) \geq \lambda c\} \). Let \( \partial B(\delta) = \{u \in \mathbb{R}^d : \|u - t\| \leq \delta \text{ for some } t \in B\} \). For any \( m > 0 \) and \( \lambda \) large, we can apply a \( \lambda \)-scaling transformation such that \( X \) under \( Q_\lambda \) and restricted to \( \partial B(m\lambda^{-1}) \) tends to \( Z \) restricted to \( \partial B \times [-m, m] \) as \( \lambda \to \infty \).

Let \( n_t \) be the unit normal vector of \( t \in \partial B \) pointing away from \( B \) and let \( \cdot \) denote the scalar or inner product of two vectors. Let

\[
Y^{(j)}(u) = \sum_{i, v^{(j)}_i \in A^{(j)}_u} Z_i \text{ for } j = 1, 2, \text{ where } A^{(1)}_u = \bigcup_{t \in \partial B : n_t \cdot u > 0} t \times [0, n_t \cdot u) \text{ and } A^{(2)}_u = \bigcup_{t \in \partial B : n_t \cdot u < 0} t \times [n_t \cdot u, 0). \tag{2.3}
\]

We define the limiting local random field

\[
Y(u) = Y^{(1)}(u) - Y^{(2)}(u), \quad u \in \mathbb{R}^d. \tag{2.4}
\]

Let

\[
I(= I_c) = \theta_c c - \sigma_d(B)[M(\theta_c) - 1]. \tag{2.5}
\]

It follows from Theorem 2.1 below that \( I = -\lim_{\lambda \to \infty} \lambda^{-1} \log p_\lambda \) and hence it is the large deviation rate of the tail probability \( p_\lambda \). If there exists \( \eta > 0 \) such that \( F \) is concentrated on \( \pm \eta, \pm 2\eta, \ldots \), then we say that \( F \) is arithmetic. The largest \( \eta \) with this property is called the span of \( F \), cf. Section 5.2 of [10]. If such \( \eta \) does not exists, then we say that \( F \) is nonarithmetic. Let \( \lfloor \cdot \rfloor \) denote the greatest integer function and \( \,''\, \) the second derivative of a function.
Theorem 2.1. Define $x_\lambda = \theta_c(\lambda c - \eta |\lambda c/\eta|)$ if $F$ is arithmetic with span $\eta$ and $x_\lambda = 0$ if $F$ is nonarithmetic. Let

$$K_m = \begin{cases} 
\eta \left[\left(1 - e^{-\eta \theta_c}\right)^{-1} 
+ \sum_{\ell \in \mathbb{Z}^+} e^{\theta_c \ell} P \left(\sup_{0 \leq u \leq m} Y(u) \geq \ell\right)\right], & \text{if } F \text{ arithmetic with span } \eta, \\
\theta_c^{-1} + \int_0^\infty e^{\theta_c y} P \left(\sup_{0 \leq u \leq m} Y(u) \geq y\right) dy, & \text{if } F \text{ nonarithmetic.}
\end{cases}$$

(2.6)

Then

$$K = \lim_{m \to \infty} m^{-d} K_m \text{ is a well-defined positive and finite constant.} \quad (2.7)$$

Moreover as $\lambda \to \infty$,

$$p_\lambda = P_\lambda \left(\sup_{v \in D} S(v + B) \geq \lambda c\right) \sim [2\pi \sigma_d(B) M''(\theta_c)]^{-1/2} e^{-\lambda L + x \lambda^{d-1/2} \sigma_d(D) K}. \quad (2.8)$$

Remark 2.1. By Jordan measurability of $D$, as $a \to 0$,

$$\# \left\{ k \in (a\mathbb{Z})^d : \prod_{j=1}^d [k_j, k_j + a) \subset D \right\} \sim \# \left\{ k \in (a\mathbb{Z})^d : \prod_{j=1}^d [k_j, k_j + a) \cap D \neq \emptyset \right\}. \quad (2.9)$$

The relation (2.8) still holds if $D$ is replaced by domains $D_\lambda$ that depends on $\lambda$, provided (2.9) holds with $D$ replaced by $D_\lambda$ and $a$ replaced by $m\lambda^{-1}$, with limit $\lambda \to \infty$ for all large $m$, and

$$\lim_{\lambda \to \infty} \lambda^{-1} \log[\sigma_d(D_\lambda)] = 0. \quad (2.10)$$

However even without condition (2.10), the relation

$$P_\lambda \left(\sup_{v \in D_\lambda} S(v + B) \geq \lambda c\right) \sim 1 - \exp\left\{-[2\pi \sigma_d(B) M''(\theta_c)]^{-1/2} e^{-\lambda L + x \lambda^{d-1/2} \sigma_d(D_\lambda) K}\right\}$$

still holds.

We next provide an alternative expression of $K$ which follows from a different proof of (2.8). This representation is less intuitive when compared to (2.6) and (2.7) but it
has the advantage of being able to provide simple bounds for $K$. Let $\sigma_d^{-1}(\cdot)$ denote the reciprocal of $\sigma_d(\cdot)$.

**Theorem 2.2.** The constant

$$K = \chi_c^{-1} E\{(1 - \exp(\theta_c \sup\{Y(u) : Y(u) < 0\}))|\sigma_d^{-1}(\{u : Y(u) = 0\})\}, \quad (2.11)$$

where $\chi_c = \eta^{-1}(1 - e^{-\eta \theta_c})$ when $F$ is arithmetic with span $\eta$ and $\chi_c = \theta_c$ when $F$ is nonarithmetic.

### 3. Examples

We first discuss two interesting cases of Theorem 2.1. In Example 3.1, we consider $F$ degenerate at 1. Then (2.8) simplifies to (3.2) below, an extension of tail probability relations in Poisson random fields obtained earlier by other authors, to non-rectangular scanning sets. In Example 3.2, we consider rectangular scanning sets on a marked Poisson random field. We show here that an overshoot constant derived from $F$ plays an important role in the tail approximations. When $F$ is degenerate at 1, that is for Poisson random fields rather than marked Poisson random fields, the overshoot constant is equal to 1 and disappears from the resulting formula. We then show in Examples 3.3 and 3.4 how the alternative expression in Theorem 2.2 leads to simple upper and lower bounds of $K$.

**Example 3.1.** Let $F$ be concentrated at 1. Then $S(v + B)$ counts the number of points $t_i$ lying inside $v + B$. Since $M(\theta) = M'(\theta) = M''(\theta) = e^\theta$, it follows from (2.2) and (2.5) that

$$e^I = \left(\frac{c}{\sigma_d(B)}\right)^c e^{-c + \sigma_d(B)}. \quad (3.1)$$
Substituting (2.2) and (3.1) into (2.8) and noting that $F$ is arithmetic with span 1, we obtain

\[ p_{\lambda} \sim (2\pi)^{-1/2} \sigma_d^{\lambda c} (B) e^{-\lambda c} e^{\lambda c - \lambda \sigma_d(B)} \lambda^{d-1/2} \sigma_d(D) K \text{ as } \lambda \to \infty. \quad (3.2) \]

**Example 3.2.** Let $B = \prod_{k=1}^d [0, b_k]$ with $b_k > 0$ for all $k$. Since $\partial B$ is a union of $2d$ faces, with a pair of them orthogonal to each co-ordinate vector, by (2.3) and (2.4),

\[ Y(u) = \sum_{k=1}^d [Y^{(1)}(u_k) - Y^{(2)}(u_k)], \]

where $Y^{(1)}_1, \ldots, Y^{(1)}_d, Y^{(2)}_1, \ldots, Y^{(2)}_d$ are independent one-dimensional compound Poisson processes. The process $Y^{(1)}_k$, $1 \leq k \leq d$, is constructed from a marked point process with intensity $\prod_{\ell \neq k} b_{\ell}$ (the surface area of the face of $B$ orthogonal to the $k$th co-ordinate vector) and mark distribution $F$. The process $Y^{(2)}_k$, $1 \leq k \leq d$, is constructed from a marked point process with intensity $M(\theta_c) \prod_{\ell \neq k} b_{\ell}$ and mark distribution $F_c$. If $X$ is a random variable with distribution $F_c$, we shall let $\bar{F}_c$ denote the distribution of $-X$. We define $\bar{F}$ in a similar manner. Consider first $F$ nonarithmetic and let $Y_k = Y^{(1)}_k - Y^{(2)}_k$. Then by (2.6) and as

\[ P\{\sup_{0 \leq u \leq m} \sum_{k=1}^d Y_k(u_k) \geq y\} = 1 \text{ for } y \leq 0, \]

\[ K_m = \int_{-\infty}^\infty e^{\theta c y} P\left(\sup_{0 \leq u \leq m} \sum_{k=1}^d Y_k(u_k) \geq y\right) dy = \theta_c^{-1} E \left\{ \exp\left(\theta_c \sum_{k=1}^d \sup_{0 \leq u_k \leq m} Y_k(u_k)\right) \right\} = \theta_c^{-1} \prod_{k=1}^d \int_{-\infty}^\infty e^{\theta c y} P\left(\sup_{0 \leq u_k \leq m} Y_k(u_k) \geq y\right) dy. \quad (3.3) \]

Since $Y^{(1)}_k$ and $Y^{(2)}_k$ are independent compound Poisson processes, it follows that $Y_k(u_k) = \sum_{j=1}^{N_k(u_k)} U_{kj}$, where $N_k$ is a Poisson process with rate parameter $(\prod_{\ell \neq k} b_{\ell})[1 + M(\theta_c)]$ and $U_{k1}, U_{k2}, \ldots$ are i.i.d. random variables independent of $N_k$ such that

\[ P(U_{k1} \in du) = [M(\theta_c) \bar{F}_c(du) + F(du)]/[1 + M(\theta_c)]. \quad (3.4) \]
Let $P_*$ be a probability measure under which the distribution of $N_k$ is unchanged and $U_{k1}, U_{k2}, \ldots$ are i.i.d. random variables independent of $N_k$ satisfying

$$P_*(U_{k1} \in du) = [\bar{F}(du) + M(\theta_c)F_c(du)]/[1 + M(\theta_c)].$$

(3.5)

By (2.2), (3.4) and (3.5),

$$(dP_*/dP)(U_{k1}) = e^{\theta_c U_{k1}}.$$

(3.6)

Suppressing the notation $k$, let $R_\ell = U_1 + \cdots + U_\ell$ and $\tau_y = \inf\{\ell \geq 1 : R_\ell \geq y\}$. Define the overshoot constant

$$\nu_c = \lim_{y \to \infty} E_*(e^{-\theta_c(R_{\tau_y} - y)}),$$

(3.7)

where $E_*$ denotes expectation with respect to $P_*$. See [23], [26] [27], [28] and Chapter 8 of [20] for analytical expressions of $\nu_c$ and also of related constants for sample size calculations. By (3.5)–(3.7),

$$\int_{-\infty}^{\infty} e^{\theta_c y} P \left( \sup_{0 \leq u_k \leq m} Y_k(u_k) \geq y \right) dy$$

$$= \theta_c^{-1} + \int_{0}^{\infty} E_*(e^{\theta_c(y-R_{\tau_y})}1_{\{\sup_{0 \leq u_k \leq m} Y_k(u_k) \geq y\}}) dy$$

$$\sim \nu_c E_*(\sup_{0 \leq u_k \leq m} Y_k(u_k)) \sim \nu_c m[c\sigma_d^{-1}(B) - \mu] \prod_{\ell \neq k} b_\ell,$$

(3.8)

noting that by (2.2), under $F_c$, $E_c(X_1) = M'(\theta_c)/M(\theta_c) = c/[\sigma_d(B)M(\theta_c)]$ and by definition, under $F$, $E(X_1) = \mu$. Substitute (3.8) into (3.3). Then by (2.7) and (2.8),

$$p_\lambda \sim \left[2\pi\sigma_d(B)M''(\theta_c)\right]^{-1/2} e^{-\chi_c \lambda + \chi_c \lambda^{d-1/2} \sigma_d(D)\{\nu_c(\sigma_d^{-1}(B) - \mu)\}} \left(\chi_c \prod_{k=1}^{d} b_k\right)^{d-1},$$

(3.9)

where $\chi_c = \theta_c$ for $F$ nonarithmetic. Using similar arguments, (3.9) can also be shown to hold for $F$ arithmetic with span $\eta$, by defining $\nu_c$ in (3.7) with $y \to \infty$ over $\eta \mathbb{Z}$ and $\chi_c = \eta^{-1}(1 - e^{-\eta \theta_c})$. 

Example 3.3. If $F$ has point mass at 1, then $\sup \{Y(u) : Y(u) < 0 \} = -1$ a.s. and by (2.11) and Jensen’s inequality,

$$K = E[\sigma_d^{-1}(\{u : Y(u) = 0\})] \geq \{E[\sigma_d(\{u : Y(u) = 0\})]\}^{-1}. \quad (3.10)$$

Let $U_d = \{t : ||t|| \leq 1\}$ be the $d$-dimensional unit ball and let

$$C_d = \frac{\sigma_{d-1}(\partial U_d)}{\sigma_{d-1}(U_{d-1})} = \frac{d\pi^{d/2}/\Gamma(d/2 + 1)}{[\pi^{(d-1)/2}/\Gamma((d + 1)/2)]^d}.$$

Then

$$E[\sigma_d(\{u : Y(u) = 0\})] = C_d \int_0^\infty r^{d-1} \sum_{k=0}^\infty e^{-r(1+c)[c^k r^{2k}/(k!)^2]} dr$$

$$= C_d \sum_{k=0}^\infty c^k \Gamma(2k + d)/[(k!)^2(1 + c)^{2k+d}] = [C_d/(1 + c)^d] f_d^{(d-1)}(\sqrt{c}/(1 + c)),$$

where $f_d(x) = x^d/\sqrt{1 - 4x^2}$ and $f_d^{(d-1)}$ is the $(d - 1)$st derivative of $f_d$. A positive lower bound of $K$ follows from (3.10). Similar computations can also be carried out for kernels of other shapes.

Example 3.4. Let $\Omega$ denote the random set of all $u$ for which the sums in (2.3) are sums over an empty set for both $j = 1$ and $j = 2$. For a more precise definition, let $\{(t_i, y_i) : i \geq 1\}$ be a Poisson point process on $\partial B \times \mathbb{R}$ with intensity 1 on $\partial B \times [0, \infty)$ and intensity $M(\theta_c)$ on $\partial B \times (-\infty, 0)$. Then

$$\Omega = \{u : y_i \geq n_t \cdot u > 0 \text{ or } y_i < n_t \cdot u < 0 \text{ for all } i\}.$$

By (2.4), $\Omega \subset \{u : Y(u) = 0\}$ and hence by (2.11),

$$K \leq \begin{cases} 
|\eta| E[\sigma_d^{-1}(\Omega)] & \text{if } F \text{ has point mass at } \eta, \\
\chi_c^{-1} E[\sigma_d^{-1}(\Omega)] & \text{otherwise}.
\end{cases}$$

The upper bound of $K$ for $F$ having point mass at $\eta$ uses the property $\sup \{Y(u) : Y(u) < 0 \} = -|\eta|$ a.s.
4. Proof of Theorem 2.1

A key idea here is a change of measure argument that allows us to obtain, in Lemma 4.1, the tail probability of the maxima over a local domain. To obtain the global probabilities in Theorem 2.1 from these local probabilities, we adapt the Pickands-Quall-Watanabe technique from the Gaussian random field literature. Hence the characterization of the constant $K$ in Theorem 2.1 bears a striking resemblance to constants seen in the earlier papers on Gaussian random fields though the distribution of $Y(u)$ here is compound Poisson rather than Gaussian. Hogan and Siegmund [12] provides a vital framework for this correspondence.

**Lemma 4.1.** Let $E_{t,m,\lambda} = \{\sup_{t \leq v \leq t+m\lambda^{-1}} S(v + B) \geq \lambda c\}$. Define $x_\lambda$ as in the statement of Theorem 2.1. Then for all $t \in D$,

$$P_\lambda(E_{t,m,\lambda}) = P_\lambda(E_{0,m,\lambda}) \sim \frac{2\pi \lambda \sigma_d(B) M''(\theta_c)}{(\lambda \sigma_d(B))^2} e^{-\lambda M + x_\lambda K_m} \text{ as } \lambda \to \infty. \quad (4.1)$$

**Proof.** By stationarity, $P_\lambda(E_{t,m,\lambda}) = P_\lambda(E_{0,m,\lambda})$. Let us first consider the case $\mathcal{F}$ arithmetic with span 1. Then

$$P_\lambda(E_{0,m,\lambda}) = P_\lambda\left(\sup_{0 \leq v \leq m\lambda^{-1}} S(v + B) \geq \lambda c\right) = P_\lambda\{S(B) \geq \lfloor \lambda c\rfloor\}$$

$$+ \sum_{\ell=1}^{\infty} P_\lambda\left(S(B) = \lfloor \lambda c\rfloor - \ell, \sup_{0 \leq v \leq m\lambda^{-1}} [S(v + B) - S(B)] \geq \ell\right). \quad (4.2)$$

Let $Q_\lambda$ be a probability measure under which $\mathcal{X}$ is a nonhomogeneous marked point process with intensity $\lambda M(\theta_c)$, mark distribution $F_\lambda$ inside $B$ and intensity $\lambda$, mark distribution $F$ outside $B$. Then

$$\frac{dQ_\lambda}{dP_\lambda}(\mathcal{X}) = \exp\{\theta_c S(B) - \lambda \sigma_d(B) [M(\theta_c) - 1]\}. \quad (4.3)$$

Let $B_\lambda = \bigcap_{0 \leq v \leq \lambda^{-1}} (v + B)$. Since $S(B \setminus B_{m\lambda^{-1}})$ and $\sup_{0 \leq v \leq m\lambda^{-1}} [S(v + B) - S(B)]$ are functions of the marked point process outside $B_{m\lambda^{-1}}$ and hence independent of
$S(B_{m\lambda^{-1}})$ under $Q_\lambda$, it follows from (4.3) that

$$P_\lambda \left( S(B) = \lfloor \lambda c \rfloor - \ell, \sup_{0 \leq v \leq m\lambda^{-1}} [S(v + B) - S(B)] \geq \ell \right)$$

$$= e^{-\lambda I + x_\theta \ell} Q_\lambda \left( S(B) = \lfloor \lambda c \rfloor - \ell, \sup_{0 \leq v \leq m\lambda^{-1}} [S(v + B) - S(B)] \geq \ell \right)$$

$$= e^{-\lambda I + x_\theta \ell} \sum_{k=0}^{\infty} Q_\lambda \left( S(B_{m\lambda^{-1}}) = \lfloor \lambda c \rfloor - \ell - k \right)$$

$$\times Q_\lambda \left( S(B \setminus B_{m\lambda^{-1}}) = k, \sup_{0 \leq v \leq m\lambda^{-1}} [S(v + B) - S(B)] \geq \ell \right). \quad (4.4)$$

It follows from the local central limit theorem that for each $\ell \in \mathbb{Z}$,

$$Q_\lambda \{ S(B_{m\lambda^{-1}}) = \lfloor \lambda c \rfloor - \ell - k \} \leq [1 + o(1)] Q_\lambda \{ S(B) = \lfloor \lambda c \rfloor - \ell \}$$

$$\sim [2\pi \lambda \sigma_d(B)M''(\theta_c)]^{-1/2} \text{ as } \lambda \to \infty, \quad (4.5)$$

uniformly over $k \geq 0$, with $\leq$ replaced by $=$ if we look at (4.5) with $k$ fixed. Hence by (4.4) and (4.5),

$$P_\lambda \left( S(B) = \lfloor \lambda c \rfloor - \ell, \sup_{0 \leq v \leq m\lambda^{-1}} [S(v + B) - S(B)] \geq \ell \right)$$

$$\sim 2\pi \lambda \sigma(B)M''(\theta_c)]^{-1/2} e^{-\lambda I + x_\theta \ell}$$

$$\times Q_\lambda \left( \sup_{0 \leq v \leq m\lambda^{-1}} [S(v + B) - S(B)] \geq \ell \right). \quad (4.6)$$

By (4.6) and the weak convergence of $\{ S(\lambda^{-1}u + B) - S(B) : 0 \leq u \leq m \}$ under $Q_\lambda$ to $\{ Y(u) : 0 \leq u \leq m \}$ as $\lambda \to \infty$, see (2.3) and (2.4),

$$\sum_{\ell=1}^{\infty} P_\lambda \left( S(B) = \lfloor \lambda c \rfloor - \ell, \sup_{0 \leq v \leq m\lambda^{-1}} [S(v + B) - S(B)] \geq \ell \right)$$

$$\sim e^{-\lambda I + x_\theta \lambda} [2\pi \lambda \sigma(B)M''(\theta_c)]^{-1/2} \sum_{\ell=1}^{\infty} e^{\theta_\ell \ell} P \left( \sup_{0 \leq u \leq m} Y(u) \geq \ell \right). \quad (4.7)$$

By a similar application of (4.3) and (4.5),

$$P_\lambda \{ S(B) \geq \lfloor \lambda c \rfloor \} \sim [2\pi \lambda \sigma_d(B)M''(\theta_c)]^{-1/2} e^{-\lambda I + x_\theta \lambda} \sum_{\ell=-\infty}^{0} e^{\theta_\ell \ell}. \quad (4.8)$$
Substitution of (4.7) and (4.8) into (4.2) then proves Lemma 4.1 when \( F \) is arithmetic with span 1. For \( F \) arithmetic with span \( \eta \), we prove Lemma 4.1 by replacing the sums in (4.2), (4.4), (4.7) and (4.8) by \( \sum_{\ell \in \eta \mathbb{Z}^+}, \sum_{k \geq 0, k \in \eta \mathbb{Z}} \) or \( \sum_{\ell \leq 0, \ell \in \eta \mathbb{Z}} \). For nonarithmetic \( F \), the sums are replaced by corresponding integrals. The details are similar to the arguments provided above and shall be omitted. □

We now proceed to the proof of Theorem 2.1. Let \( J = [0, 1]^d, \mathcal{C}_a = \{k \in (a\mathbb{Z})^d : k + aJ \subset D\} \) and \( \overline{\mathcal{C}}_a = \{k \in (a\mathbb{Z})^d : k + aJ \cap D \neq \emptyset\} \). Then \( \{k + aJ : k \in \mathcal{C}_a\} \) and \( \{k + aJ : k \in \overline{\mathcal{C}}_a\} \) are lower and upper coverings of \( D \) respectively by cubes of length \( a \). We shall show via Lemmas 4.2 and 4.3 below that

\[
\lim_{m \to \infty} \limsup_{\lambda \to \infty} \left[ \sum_{u \in \mathcal{C}_{m \lambda - 1}} P_\lambda \left( \bigcup_{w \in \mathcal{C}_{m \lambda - 1} : w \neq u} (E_{u,m,\lambda} \cap E_{w,m,\lambda}) \right) / (\lambda^{d-1/2} e^{-\lambda I}) \right] = 0.
\]

(4.9)

The proofs of Lemmas 4.2, 4.3 and (4.9) will be given in the Appendix. Let \( f(\lambda) = [2\pi \sigma_d(B) M''(\theta_c)]^{-1/2} \lambda^{d-1/2} e^{-\lambda I + x_\lambda} \). Then by Lemma 4.1,

\[
P_\lambda(E_{u,m,\lambda}) \sim K_m f(\lambda) / \lambda^d \quad \text{as} \quad \lambda \to \infty.
\]

(4.10)

Given \( \epsilon > 0 \), let \( m_\epsilon \) be large enough such that for all \( m \geq m_\epsilon \), the expression in the square brackets on the left-hand side of (4.9) does not exceed \( \epsilon \) for all large \( \lambda \). Then by (4.10), for all \( m \geq m_\epsilon \),

\[
\liminf_{\lambda \to \infty} [\lambda^{-d}(\#\mathcal{C}_{m \lambda}) K_m - \epsilon \lambda^{d-1/2} e^{-\lambda I} / f(\lambda)] \leq \liminf_{\lambda \to \infty} [p_\lambda / f(\lambda)]
\]

\[
\leq \limsup_{\lambda \to \infty} [p_\lambda / f(\lambda)] \leq \limsup_{\lambda \to \infty} [\lambda^{-d}(\#\overline{\mathcal{C}}_{m \lambda}) K_m].
\]

(4.11)

Since \( D \) is Jordan-measurable,

\[
\#\mathcal{C}_a \sim \#\overline{\mathcal{C}}_a \sim a^{-d} \sigma_d(D) \quad \text{as} \quad a \to 0.
\]

(4.12)
Noting that \( \liminf_{\lambda \to \infty} [p_{\lambda}/f(\lambda)] \) and \( \limsup_{\lambda \to \infty} [p_{\lambda}/f(\lambda)] \) are fixed real numbers and \( x_\lambda \) is bounded, it follows from (4.11) and (4.12) that \( m^{-d}K_m \) is Cauchy. Hence \( K = \lim_{m \to \infty} m^{-d}K_m \) exists and (2.8) follows from (4.11).

We will now state Lemmas 4.2 and 4.3 before proving Theorem 2.1. To avoid repetitive arguments, we will state and prove all subsequent results in this section and in the appendices assuming \( F \) is arithmetic with span 1. The modifications required to extend these results to arbitrary \( F \) are straightforward and will not be discussed.

**Lemma 4.2.**

\[
\lim_{r \to \infty} \limsup_{\lambda \to \infty} \left[ P_\lambda \left( S(B) < \lfloor \lambda c \rfloor - r, \sup_{0 \leq v \leq \lambda^{-1}} S(v + B) \geq \lfloor \lambda c \rfloor - r \right) \right] = 0.
\]

**Lemma 4.3.** Let \( r \geq 0 \) and \( L > 0 \) be given. Then

\[
\lim_{k \to \infty} \limsup_{\lambda \to \infty} \sum_{v \in (\lambda^{-1})^d, \|v\| \leq L} P_\lambda \left( S(v + B) \geq \lfloor \lambda c \rfloor - r \right) = O(\lambda^{-1/2}e^{-\lambda I}).
\]

**Proof of Theorem 2.1.** By the arguments in (4.9)–(4.12), it remains for us to show that \( K \) is positive and finite. By Lemma 4.2, there exists \( r \) large enough such that

\[
P_\lambda \left( S(B) < \lfloor \lambda c \rfloor - r, \sup_{0 \leq v \leq \lambda^{-1}} S(v + B) \geq \lfloor \lambda c \rfloor \right) \leq \lambda^{-1/2}e^{-\lambda I}
\]

for all large \( \lambda \). Moreover, by a modification of (4.8) (with \( \sum_{\ell=-\infty}^r \) in place of \( \sum_{\ell=-\infty}^0 \)),

\[
P_\lambda \{ S(B) \geq \lfloor \lambda c \rfloor - r \} = O(\lambda^{-1/2}e^{-\lambda I}).
\]

By adding up (4.13), (4.14) and applying Lemma 4.1, we show that \( K_1 < \infty \). Then by (2.8), (4.11) and (4.12), \( K \leq K_1 < \infty \).

Next, select \( \epsilon \) small enough such that \( \delta = [2\pi \sigma_d(B)M''(\theta_c)]^{-1/2} \sum_{\ell=-\infty}^0 e^{\theta_c \ell - \epsilon} > 0 \). By Lemma 4.3 with \( r = 0 \) and \( L > \sup_{x,y \in D} \|x - y\| \), there exists \( k \) large enough
such that
\[ \sum_{v \in (k \lambda^{-1} \mathbb{Z})^d : 0 < \|v\|_\infty \leq L} P_{\lambda}\{S(B) \geq [\lambda c], S(v + B) \geq [\lambda c]\} \leq \epsilon \lambda^{-1/2} e^{-\lambda t} \] (4.15)
for all large \( \lambda \). Then by stationarity, (4.8) and (4.15), noting that \( x_\lambda \geq 0 \),
\[ P_{\lambda}(E_{0,m,\lambda}) \geq P_{\lambda}\{S(u + B) \geq [\lambda c] \text{ for some } u \in (k \lambda^{-1} \mathbb{Z})^d, 0 \leq u \leq m \lambda^{-1}\} \]
\[ \geq \sum_{u \in (k \lambda^{-1} \mathbb{Z})^d : 0 \leq u \leq m \lambda^{-1}} \left( P_{\lambda}\{S(u + B) \geq [\lambda c]\} - \sum_{w \in (k \lambda^{-1} \mathbb{Z})^d : 0 < \|w - u\|_\infty \leq L} P\{S(u + B) \geq [\lambda c], S(w + B) \geq [\lambda c]\} \right) \]
\[ \geq \left(\frac{m}{k}\right)^d \delta \lambda^{-1/2} e^{-\lambda t} \text{ for all large } \lambda, \]
and by letting \( m \to \infty \) with \( k \) fixed, it follows from (2.7), (4.1) and \( x_\lambda \) bounded that \( K > 0 \). \( \square \)

5. Proof of Theorem 2.2

The key trick here is a telescoping sum of (5.3) or (5.5) below which removes the dependence of the representation of \( K \) on the supremum of \( Y \). To simplify notations, we shall first consider \( F \) having point mass at 1, select \( \lambda \) such that \( x_\lambda = 0 \) (i.e. \( \lambda c \in \mathbb{Z} \)) and write \( S(v) \) in place of \( S(v + B) \). Let
\[ p_c(t, k, dw) = P_{\lambda}\left( \sup_{v \in D} S(v) = \lambda c, S(t) = \lambda c - k, \sigma_d(\{v \in D : S(v) = \lambda c - k\}) \in \lambda^{-d} dw \right). \] (5.1)
By the change of measure argument in the proof of Lemma 4.1, in particular (4.4) and (4.5), and Lemmas 4.2 and 4.3, for any integer \( k \geq 0 \), \( t \) lying in the interior of \( D \) and \( dw \in (0, \infty) \),
\[ p_c(t, k, dw) = e^{-\lambda t + \theta_k} Q_{\lambda}\{S(t) = \lambda c - k\} Q_{\lambda}\left( \sup_{v \in D} [S(v) - S(t)] = k \right). \]
\[
\sigma_d(\{ v \in D : [S(v) - S(t)] = 0 \}) \in \lambda^{-d} dw \bigg| S(t) = \lambda c - k
\]
\[
\sim \left[ 2\pi \lambda \sigma_d(B) M''(\theta_c) \right]^{-1/2} e^{-\lambda t + \theta c k} \\
\times \mathbb{P} \left( \sup_{u \in \mathbb{R}^d} (u : Y(u) = 0) \right) = \mathbb{P} \left( \mathbb{P} \left( \sup_{u \in \mathbb{R}^d} (u : Y(u) = 0) \right) \right).
\] 

(5.2)

The second relation in (5.2) follows from the weak convergence of \( S(\lambda^{-1} u + t) - S(t) : 0 \leq u \leq m \), under \( \mathbb{Q}_\lambda \) and with conditioning on \( S(t) = \lambda c - k \), to \( \{ Y(u) : 0 \leq u \leq m \} \). Multiplying \( p_c(t, k, dw) \) by \( \lambda^d (e^{-\theta c k} - e^{-\theta c(k+1)}) / w \) and integrating over \( t \in D \) and \( w > 0 \), we obtain, from (5.1) and (5.2),

\[
(e^{-\theta c k} - e^{-\theta c(k+1)}) P_\lambda \left( \sup_{v \in D} S(v) = \lambda c, S(t) = \lambda c - k \text{ for some } t \in D \right) = \lambda^d (e^{-\theta c k} - e^{-\theta c(k+1)}) \\
\times \mathbb{P} \left( \mathbb{P} \left( \sup_{u \in \mathbb{R}^d} (u : Y(u) = 0) \right) \right) \mathbb{P} \left( \sup_{u \in \mathbb{R}^d} (u : Y(u) = 0) \right).
\] 

(5.3)

We then sum up over \( 0 \leq k \leq k_0 \), let \( \lambda \to \infty \) followed by \( k_0 \to \infty \), and compare against the asymptotic relation

\[
P_\lambda \left( \sup_{v \in D} S(v) = \lambda c \right) \sim \left[ 2\pi \sigma_d(B) M''(\theta_c) \right]^{-1/2} (1 - e^{-\theta c}) e^{-\lambda t \theta c} \lambda^d/2 \sigma_d(D) K, \quad (5.4)
\]

which follows from a straightforward modification of Theorem 2.1, to obtain the expression \( K = E[\sigma_\lambda^{-1}(\{ u : Y(u) = 0 \})] \).

Let us next consider more generally \( F \) arithmetic with span 1. Let \( k_0 > 0 \) and when the event \( \{ \sup_{v \in D} S(v) = \lambda c \} \) occurs, let \( \{ r_i : 1 \leq i \leq I \} \) be a monotone rearrangement of \( \{ \lambda c - S(t) : t \in D, 0 \leq \lambda c - S(t) \leq k_0 \} \). In other words, \( 0 = r_0 < r_1 < \cdots < r_I \leq k_0 \).

Define for \( 0 \leq k < \ell \leq k_0 \),

\[
p_c(t, k, \ell, dw) = P \left( \sup_{v \in D} S(v) = \lambda c, \lambda c - S(t) = k = r_i \text{ and } \ell = r_{i+1} \text{ for some } i, \sigma_d(\{ v : S(v) = \lambda c - k \}) \in \lambda^{-d} dw \right).
\]
Maxima of moving sums

Then by the arguments in (5.2) and (5.3),
\[
(e^{-\theta_c k} - e^{-\theta_c \ell}) P_{\lambda}(\sup_{v \in D} S(v) = \lambda c, r_i = k, r_{i+1} = \ell \text{ for some } i)
\]
\[
= \lambda^d (e^{-\theta_c k} - e^{-\theta_c \ell}) \int_{D} \int_{0}^{\infty} [p_c(t, k, \ell, dw)/w] dt
\]
\[
\sim [2 \pi \sigma_d(B) M''(\theta_c)]^{-1/2} e^{-\lambda^d/2} \sigma_d(D)(1 - e^{-\theta_c (\ell - k)})
\]
\[
\times E[\sigma_d^{-1}(\{|u: Y(u) = 0\}|1_{\{\sup_{u \in D} Y(u) = k, \sup_{u \in D}: Y(u) < 0 Y(u) = k - \ell\})}. (5.5)
\]

We then sum up (5.5) over all integers 0 \leq k < \ell \leq k_0, let \lambda \to \infty followed by 
k_0 \to \infty, and compare against (5.4) to obtain the more general expression (2.11). For 
F arithmetic with span \eta, the arguments are similar while for nonarithmetic F, we need to partition the range of \(S(t), \ t \in D,\) into intervals of length \(\epsilon,\) then let \(\epsilon \to 0.\)

The details are omitted.

6. Extension of representation to Gaussian random fields

Let \(X(t), \ t \in \mathbb{R}^d\) be a stationary, mean zero, continuous Gaussian random field 
satisfying
\[
E[X(t)X(t+s)] \sim 1 - a\|s\|^\alpha \text{ as } \|s\| \to 0,
\]
for some 0 < \(\alpha \leq 2\) and \(a > 0.\) Let \(\Delta_c = (\epsilon^2 a)^{-1/\alpha}.\) It was shown in [6], [16], [18] that 
\[
P\left(\sup_{t \in D} X(t) \geq c\right) \sim (2\pi)^{-1/2} c^{-1/2} e^{-c^2/2} \Delta_c^{-d/2} \sigma_d(D) \tilde{K} \text{ as } c \to \infty \quad (6.1)
\]
for some \(\tilde{K} > 0\) which is expressed in terms of a continuous Gaussian random field \(\tilde{Y}\) 
satisfying
\[
E[\tilde{Y}(u)] = -\|u\|^\alpha, \quad \text{cov}(\tilde{Y}(u), \tilde{Y}(v)) = \|u\|^\alpha + \|v\|^\alpha - \|u - v\|^\alpha. \quad (6.2)
\]
In particular,
\[
\tilde{K} = \lim_{m \to \infty} m^{-d} \int_{0}^{\infty} e^y P\left(\sup_{0 \leq u \leq m} \tilde{Y}(u) \geq y\right) dy.
\]
The key argument in the proof of (6.1) is the weak convergence

\[ \{c[X(t + \Delta c u) - X(t)] : 0 \leq u \leq m \} \Rightarrow \{\tilde{Y}(u) : 0 \leq u \leq m \} \text{ for any } m > 0, \]  

(6.3)

conditioned on \( X(t) = c - y/c \) for some \( y > 0 \). In Theorem 6.1, we apply the approach of Section 5 to obtain a different representation of \( \tilde{K} \), one that involves only the occupation measure of \( \tilde{Y} \) near 0.

**Theorem 6.1.** \( \tilde{K} = \lim_{\xi \to 0} \int_0^\xi E[\sigma_d^{-1}\{u : -b < \tilde{Y}(u) \leq \xi - b\}] \, db. \)

**Example 6.1.** By Theorem 6.1 and Jensen’s inequality,

\[ \tilde{K} \geq \limsup_{\xi \to 0} \int_0^\xi \{E[\sigma_d(\{u : -b < \tilde{Y}(u) \leq \xi - b\})]\}^{-1} \, db = \left( \int_{\mathbb{R}^d} f_t(0) \, dt \right)^{-1}, \]  

(6.4)

where \( f_t \) denotes the normal density of \( \tilde{Y}(t) \), with means and variances given in (6.2).

Let \( U_d = \{t : ||t|| \leq 1\} \). Then by (6.4),

\[ \tilde{K} \geq \left( \sigma_{d-1}(\partial U_d) \int_0^\infty r^{d-1}(4\pi r^\alpha)^{-1/2}e^{-r^{2\alpha}/(4r^\alpha)} \, dr \right)^{-1} = d^{-1} \pi^{(1-d)/2} 4^{1-d/\alpha} \alpha \Gamma \left( \frac{d}{2} + 1 \right) / \Gamma \left( \frac{d}{\alpha} - \frac{1}{2} \right). \]  

(6.5)

In the case \( \alpha = 2 \), \( \tilde{Y} \) has a simple characterization from which \( \tilde{K} = \pi^{-d/2} \) can be computed. For \( d = 2 \), the second line of (6.5) is \( \pi^{-1}(=\tilde{K}) \) and for \( d = 3 \), it is \( (4\sqrt{\pi})^{-1} \).

It is quite straightforward to improve upon (6.5). Consider \( 0 < \alpha < 2 \) and select \( t \neq 0 \). Let \( f_{s|t}(\cdot|y) \) denote the density of \( \tilde{Y}(s) \) conditioned on \( \tilde{Y}(t) = y \). Then by a more refined application of Jensen’s inequality,

\[ \tilde{K} \geq \int_{-\infty}^\infty \left[ \int_{\mathbb{R}^d} f_{s|t}(0|y) \, ds \right]^{-1} f_t(y) \, dy. \]

In principle, we can get even sharper computable lower bounds by conditioning on two or more \( t \)'s.
Proof of Theorem 6.1. Let \( \xi > 0, 0 \leq v < \xi, X_{\text{sup}} = \sup_{t \in D} X(t) \) and \( Y_{\text{sup}} = \sup_{u \in \mathbb{R}} \tilde{Y}(u) \). Let \( k \) be a non-negative integer, \( I_k = (X_{\text{sup}} + [v - (k + 1)\xi])/c, X_{\text{sup}} + (v - k\xi)/c \) and \( J_k = [k\xi - v, (k + 1)\xi - v) \). Define

\[
g_{c,\xi,v}(t, k, dw) = P\{X_{\text{sup}} \geq c, X(t) \in I_k, \sigma_d(\{u \in D : X(u) \in I_k\}) \in \Delta_d dw\}.
\]

By (6.3), for any \( t \) lying in the interior of \( D \) and \( dw \in (0, \infty) \),

\[
g_{c,\xi,v}(t, k, dw) \sim (2\pi)^{-1/2} e^{-t^2/2} \int_{-\infty}^{\infty} e^y P\{X_{\text{sup}} \geq c, X(t) \in I_k, \sigma_d(\{u \in D : X(u) \in I_k\}) \in \Delta_d dw\} X(t) = c - y/c \, dy \\
\sim (2\pi)^{-1/2} e^{-t^2/2} \left\{ \left( \int_{-\infty}^{k\xi - v} e^y \, dy \right) \times P\{Y_{\text{sup}} \in J_k, \sigma_d(\{u : Y_{\text{sup}} - \tilde{Y}(u) \in J_k\}) \in dw\} \\
+ \int_{k\xi - v}^{(k+1)\xi - v} e^y P\{y \leq Y_{\text{sup}} < (k + 1)\xi - v, \sigma_d(\{u : Y_{\text{sup}} - \tilde{Y}(u) \in J_k\}) \in dw\} \, dy \right\}. \tag{6.6}
\]

Multiply (6.6) by \( (e^{-k\xi} - e^{-(k+1)\xi})/(\Delta_d dw) \), integrate over \( t \in D \) and \( w > 0 \), then add over \( 0 \leq k \leq k_0 \) for some positive integer \( k_0 > 0 \). We obtain

\[
\sum_{k=0}^{k_0} (e^{-k\xi} - e^{-(k+1)\xi}) P\{X_{\text{sup}} \geq c, X(t) \in I_k \text{ for some } t \in D\} \\
= \Delta_c^{-d} \sum_{k=0}^{k_0} (e^{-k\xi} - e^{-(k+1)\xi}) \int_D \int_0^\infty [g_{c,\xi,v}(t, k, dw)/w] \, dt \\
\sim (2\pi)^{-1/2} e^{-t^2/2} \Delta_c^{-d} \sigma_d(D) \left\{ (e^{-v} - e^{-v-\xi}) \sum_{k=0}^{k_0} E[1_{\{Y_{\text{sup}} \in J_k\}}] \\
\times \sigma_d^{-1}(\{u : Y_{\text{sup}} - \tilde{Y}(u) \in J_k\}) + o_\xi(1) \right\}, \tag{6.7}
\]

where \( o_\xi(1) \to 0 \) as \( \xi \to 0 \). Since \( Y_{\text{sup}} \in J_k \) is equivalent to \( k = \lfloor (Y_{\text{sup}} + v)/\xi \rfloor \), by (6.1), (6.7) and letting \( k_0 \to \infty \),

\[
\bar{K} = \lim_{\xi \to 0} \int_0^\xi E[\sigma_d^{-1}(\{u : Y_{\text{sup}} - (\xi \lfloor (Y_{\text{sup}} + v)/\xi \rfloor - v - \xi) \\
< \tilde{Y}(u) \leq Y_{\text{sup}} - (\xi \lfloor (Y_{\text{sup}} + v)/\xi \rfloor - v))\} \, dv,
\]

Maxima of moving sums
and Theorem 6.1 is shown. □

Appendix A. Proof of Lemma 4.2

By (4.6) with \( m = 1 \) and the weak convergence of \( S(\lambda^{-1}u + B) - S(B) \) to \( Y(u) \) under \( Q_\lambda \), as \( \lambda \to \infty \),

\[
P_\lambda \left( S(B) < [\lambda c] - r, \sup_{0 \leq v \leq \lambda^{-1}} S(v + B) \geq [\lambda c] \right) \\
\sim \left[ 2\pi \lambda \sigma_d(B) M''(\theta_c) \right]^{-1/2} e^{-\lambda M + x_\lambda} \sum_{\ell = r + 1}^{\infty} e^{\theta_\ell} P_\lambda \left( \sup_{0 \leq u \leq 1} Y(u) \geq \ell \right). \tag{A.1}
\]

Let \( x^+ = \max\{x, 0\} \) and \( x^- = \max\{-x, 0\} \). It follows from (2.3) and (2.4) that

\[
\sup_{0 \leq u \leq 1} Y(u) \leq Z^* = \sum_{i:v_i^{(1)} \in A^{(1)}} [Z_i^{(1)}]^+ + \sum_{i:v_i^{(2)} \in A^{(2)}} [Z_i^{(2)}]^-, \tag{A.2}
\]

where \( A^{(1)} = \partial B \times [0, 1/2] \) and \( A^{(2)} = \partial B \times [-1/2, 0) \). We can also express \( Z^* = \sum_{j=1}^{N} V_j \), where \( N \) is a Poisson random variable with mean \( \kappa = 1 - F(0) + M(\theta_c)F_c(0) \) and \( V_1, V_2, \ldots \) are i.i.d. random variables independent of \( N \) with \( g = E(e^{\tilde{\theta} V_1}) < \infty \) for some \( \tilde{\theta} > \theta_c \). Since \( E(e^{\tilde{\theta} Z^*}) = e^{\kappa(g-1)} \), it follows from Chebyshev’s inequality that

\[
P(Z^* \geq \ell) \leq e^{\kappa(g-1)-\tilde{\theta} \ell}. \ 	ext{Hence by (A.2),}
\]

\[
\sum_{\ell = r + 1}^{\infty} e^{\theta_\ell} P_\lambda \left( \sup_{0 \leq u \leq 1} Y(u) \geq \ell \right) = O(e^{\kappa(g-1)-(\tilde{\theta}-\theta_c) r}). \tag{A.3}
\]

Since \( x_\lambda \) is bounded, Lemma 4.2 follows from (A.1) and (A.3).

Appendix B. Proof of Lemma 4.3

Let \( \tilde{Q}_\lambda = \tilde{Q}_{\lambda,v} \) be the probability measure under which the marked point process \( \mathcal{X} \) has intensity \( \lambda M(\theta_c) \) on \( B_1 = B \cap (v + B) \), intensity \( \lambda M(\theta_c/2) \) on \( B_2 = \{B \setminus (v + B)\} \cup \{(v + B) \setminus B\} \) and intensity \( \lambda \) elsewhere on \( \mathbb{R}^d \). We also require that under \( \tilde{Q}_\lambda \), the marks
have distribution $F_c$ on $B_1$, distribution $\tilde{F}$ satisfying $\tilde{F}(dx) = e^{\theta_c x/2}F(dx)/M(\theta_c/2)$ on $B_2$ and $F$ elsewhere on $\mathbb{R}^d$. Then

$$
\frac{d\tilde{Q}_\lambda(X)}{dP_\lambda(X)} = \prod_{i: i \in B_1} \exp(\theta_c X_i) \exp\{ -\lambda \sigma_d(B_1)[M(\theta_c) - 1] \} \times \prod_{i: i \in B_2} \exp(\theta_c X_i/2) \exp\{ -\lambda \sigma_d(B_2)[M(\theta_c/2) - 1] \}. \quad (B.1)
$$

Since $M$ is convex and $M(0) = 1$, $\zeta = [M(\theta_c) - 1] - 2[M(\theta_c/2) - 1] > 0$. We can thus express $(B.1)$ as

$$
\frac{d\tilde{Q}_\lambda(X)}{dP_\lambda(X)} = \exp\{ (\theta_c/2)[S(B) + S(v + B)] - \lambda \sigma_d(B) + \sigma_d(v + B)\} \exp\{ [M(\theta_c) - 1]/2 + \lambda \zeta \sigma_d(B_2)/2 \},
$$

and it follows from (2.5) and an analogue of (4.5) that

$$
P_\lambda\{ S(B) \geq [\lambda c] - r, S(v + B) \geq [\lambda c] - r \} \leq P_\lambda\{ S(B) + S(v + B) \geq 2([\lambda c] - r) \}
$$

$$
= E_{\tilde{Q}_\lambda} \left( \frac{dP_\lambda}{d\tilde{Q}_\lambda} 1_{\{ S(B) + S(v + B) \geq 2([\lambda c] - r) \}} \right) = O(e^{-\lambda - \lambda \zeta \sigma_d(B(v + B)) \lambda^{-1/2}}). \quad (B.2)
$$

Let $\|e\| = 1$ and let $\Pi_e = \{ b - (e \cdot b)e : b \in B \}$ be the projected surface of $B$ on a $(d - 1)$-dimensional hyperplane orthogonal to $e$. Then $\beta = \inf_{\|e\| = 1} \sigma_d^{-1}(\Pi_e) > 0$. Hence there exists $\epsilon > 0$ such that

$$
\sigma_d(B \setminus (v + B)) \geq \|v\|\beta/2 \geq \|v\|_{\infty}\beta/2 \text{ for all } \|v\|_{\infty} \leq \epsilon. \quad (B.3)
$$

By $(B.2)$ and $(B.3)$, it follows that

$$
\sum_{v \in (\lambda^{-1}2^d)^d : \|v\| \leq \epsilon} P_\lambda\{ S(B) \geq [\lambda c] - r, S(v + B) \geq [\lambda c] - r \}
$$

$$
= O\left( \lambda^{-1/2}e^{-\lambda} \sum_{k \geq \epsilon} e^{-k\epsilon\beta/2} \right) = O(\lambda^{-1/2}e^{-\lambda}k^{d-1}e^{-\epsilon k\beta/2}). \quad (B.4)
$$

Since $\alpha = \inf_{\|v\|_{\infty} > \epsilon} \sigma_d(B \setminus (v + B)) > 0$, it also follows from $(B.2)$ that

$$
\sum_{v \in (\lambda^{-1}2^d)^d : \|v\| \leq L} P_\lambda\{ S(B) \geq [\lambda c] - r, S(v + B) \geq [\lambda c] - r \} = O(\lambda^{d-1/2}e^{-\lambda} - \lambda \zeta \alpha). \quad (B.5)
$$
Lemma 4.3 then follows from combining (B.4) and (B.5).

Appendix C. Proof of (4.9)

Let $\epsilon > 0$. By Lemma 4.2 and stationarity, we can select $r$ large enough such that

$$
\gamma_{u,\lambda} = P_{\lambda} \left( S(u + B) < \lfloor \lambda c \rfloor - r, \sup_{u \leq v \leq u+1} S(v + B) \geq \lfloor \lambda c \rfloor \right) \leq \epsilon \lambda^{-1/2} e^{-\lambda I} \tag{C.1}
$$

for all large $\lambda$. Let $k = \lfloor m^{1/2} \rfloor$, $\Gamma_m = \{ t \in \mathbb{Z}^d : k \leq t \leq (m - k) \}$ and $\Omega_m = \{ t \in \mathbb{Z}^d : 0 \leq t \leq m \} \setminus \Gamma_m$. Then

$$
\sum_{u \in \mathcal{C}_{m-1}} P_{\lambda} \left( \bigcup_{w \in \mathcal{C}_{m-1} : w \neq u} (E_{u,m,\lambda} \cap E_{w,m,\lambda}) \right) \leq \sum_{u \in \mathcal{C}_{m-1}} \gamma_{u,\lambda} + \sum_{u \in \mathcal{C}_{m-1}} P_{\lambda}(G_{u,m,\lambda} \cap G_{w,m,\lambda}) + \sum_{u \in \mathcal{C}_{m-1}} P_{\lambda}(H_{u,m,\lambda}), \tag{C.2}
$$

where

$$
G_{u,m,\lambda} = P_{\lambda} \{ S(v + B) \geq \lfloor \lambda c \rfloor - r \text{ for some } v \in u + \lambda^{-1} \Gamma_m \}, \tag{C.3}
$$

$$
H_{u,m,\lambda} = P_{\lambda} \{ S(v + B) \geq \lfloor \lambda c \rfloor - r \text{ for some } v \in u + \lambda^{-1} \Omega_m \}. \tag{C.4}
$$

By (4.12) and (C.1),

$$
\sum_{u \in \mathcal{C}_{m-1}} \gamma_{u,\lambda} \leq \lfloor \epsilon + o(1) \rfloor \lambda^{d-1/2} e^{-\lambda I} \sigma_d(D). \tag{C.5}
$$

Let $L > \sup_{x,y \in \mathcal{D}} \|x - y\|_\infty$. Then by (C.3), stationarity and Lemma 4.3, there exists $m$ large enough such that for all $u \in \mathcal{C}_{m\lambda^{-1}}$ and large $\lambda$,

$$
\sum_{w \in \mathcal{C}_{m\lambda^{-1}} : w \neq u} P_{\lambda}(G_{u,m,\lambda} \cap G_{w,m,\lambda}) \leq m^d \sum_{v \in (\lambda^{-1} \mathbb{Z})^d : \|v\|_\infty \leq L} P_{\lambda} \{ S(B) \geq \lfloor \lambda c \rfloor - r, S(v + B) \geq \lfloor \lambda c \rfloor - r \} \leq \lfloor \epsilon + o(1) \rfloor m^d \lambda^{-1/2} e^{-\lambda I}.
$$
Maxima of moving sums

Hence by (4.12),

$$
\sum_{u, w \in C_{m, \lambda - 1}, w \neq u} P_{\lambda}(G_{u, m, \lambda} \cap G_{w, m, \lambda}) \leq \sigma_d(D)[\epsilon + o(1)]\lambda^{d-1/2}e^{-\lambda I}.
$$

(C.6)

Since \(k = \lfloor m^{1/2} \rfloor\), it follows that \(#\Omega_m = (m + 1)^d - (m + 1 - 2k)^d = O(m^{d-1/2})\). By (4.12), (C.4) and a modification of (4.8) (with \(\sum_{\ell = -\infty}^r\) in place of \(\sum_{\ell = -\infty}^0\)),

$$
\sum_{u \in C_{m, \lambda - 1}} P_{\lambda}(H_{u, m, \lambda}) = O(m^{d-1/2}(\lambda m^{-1})^d \sigma_d(D) \lambda^{-1/2} e^{-\lambda I}) \leq \epsilon \lambda^{d-1/2} e^{-\lambda I} \sigma_d(D)
$$

(C.7)

for all large \(m\). We then obtain (4.9) from (C.2) and (C.5)–(C.7) by choosing \(\epsilon\) arbitrarily small.
